

CS 201: Data Structure and Algorithm

Strongly Connected Component

Last Class's Topic

- DFS
- Topological Sort
- Problems:
 - Detect cycle in an undirected graph
 - Detect cycle in a directed graph
 - How many paths are there from “s” to “t” in a directed acyclic graph?

Connectivity

- Connected Graph
 - In an **undirected graph** G , two vertices u and v are called connected if G contains a path from u to v . Otherwise, they are called disconnected.
 - A **directed graph** is called connected if every pair of distinct vertices in the graph is connected.
- Connected Components
 - A connected component is a **maximal connected subgraph** of G . Each vertex belongs to exactly one connected component, as does each edge.

Connectivity (cont.)

- Weakly Connected Graph

- A directed graph is called **weakly connected** if **replacing** all of its directed edges with **undirected edges** produces a connected (undirected) graph.

- Strongly Connected Graph

- It is strongly connected or strong if it contains a directed path from u to v for every pair of vertices u, v . The strong components are the maximal strongly connected subgraphs

Connected Components

- Strongly connected graph
 - A directed graph is called *strongly connected* if for every pair of vertices u and v there is a path from u to v and a path from v to u .
- Strongly Connected Components (SCC)
 - The **strongly connected components (SCC)** of a directed graph are its maximal strongly connected subgraphs.
- Here, we work with
 - Directed unweighted graph

Strongly Connected Components

- G is strongly connected if every pair (u, v) of vertices in G is reachable from one another.
- A **strongly connected component** (**SCC**) of G is a maximal set of vertices $C \subseteq V$ such that for all $u, v \in C$, both $u \rightsquigarrow v$ and $v \rightsquigarrow u$ exist.

DFS - Strongly Connected Components

DFS - Strongly Connected Components

Component Graph

- $G^{\text{SCC}} = (V^{\text{SCC}}, E^{\text{SCC}})$.
- V^{SCC} has one vertex for each SCC in G .
- E^{SCC} has an edge if there's an edge between the corresponding SCC's in G .
- G^{SCC} for the example considered:

Strongly Connected Components

The **transpose** M^T of an $N \times N$ matrix M is the matrix obtained when the rows become columns and the column become rows:

Transpose of a Directed Graph

- $G^T =$ **transpose** of directed G .
 - $G^T = (V, E^T)$, $E^T = \{(u, v) : (v, u) \in E\}$.
 - G^T is G with all edges reversed.
- Can create G^T in $\Theta(V + E)$ time if using adjacency lists.
- G and G^T have the *same* SCC's. (u and v are reachable from each other in G if and only if reachable from each other in G^T .)

Algorithm to determine SCCs

SCC(G)

1. call DFS(G) to compute finishing times $f[u]$ for all u
2. compute G^T
3. call DFS(G^T), but in the main loop, consider vertices in order of decreasing $f[u]$ (as computed in first DFS)
4. output the vertices in each tree of the depth-first forest formed in second DFS as a separate SCC

Time: $\Theta(V + E)$.

Example

DFS on the initial graph G

b	e	a	c	d	g	h	f
16	15	14	10	9	7	6	4

DFS on G^T :

- start at b : visit a, e
- start at c : visit d
- start at g : visit f
- start at h

Strongly connected components: $C_1 = \{a, b, e\}$, $C_2 = \{c, d\}$, $C_3 = \{f, g\}$, $C_4 = \{h\}$

Component Graph

- The **component graph** $G^{\text{SCC}} = (V^{\text{SCC}}, E^{\text{SCC}})$:
 - $V^{\text{SCC}} = \{v_1, v_2, \dots, v_k\}$, where v_i corresponds to each strongly connected component \mathcal{C}_i
 - There is an edge $(v_i, v_j) \in E^{\text{SCC}}$ if G contains a directed edge (x, y) for some $x \in \mathcal{C}_i$ and $y \in \mathcal{C}_j$
- The component graph is a DAG

Lemma 1

Let C and C' be distinct SCCs in G

Let $u, v \in C$, and $u', v' \in C'$

Suppose there is a path $u \Rightarrow u'$ in G

Then there cannot also be a path $v' \Rightarrow v$ in G .

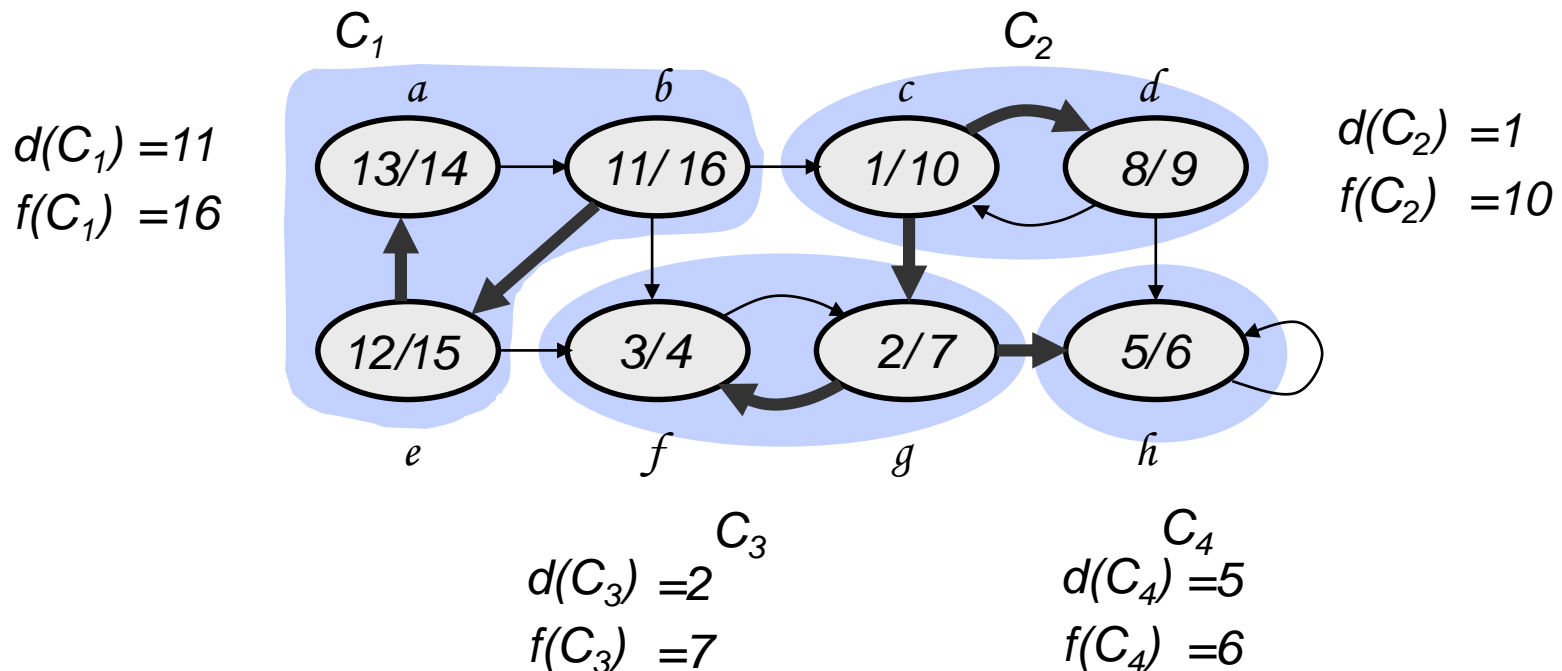

Proof

- Suppose there is a path $v' \Rightarrow v$
- There exists $u \Rightarrow u' \Rightarrow v'$
- There exists $v' \Rightarrow v \Rightarrow u$
- u and v' are reachable from each other, so they are not in separate SCC's: contradiction!

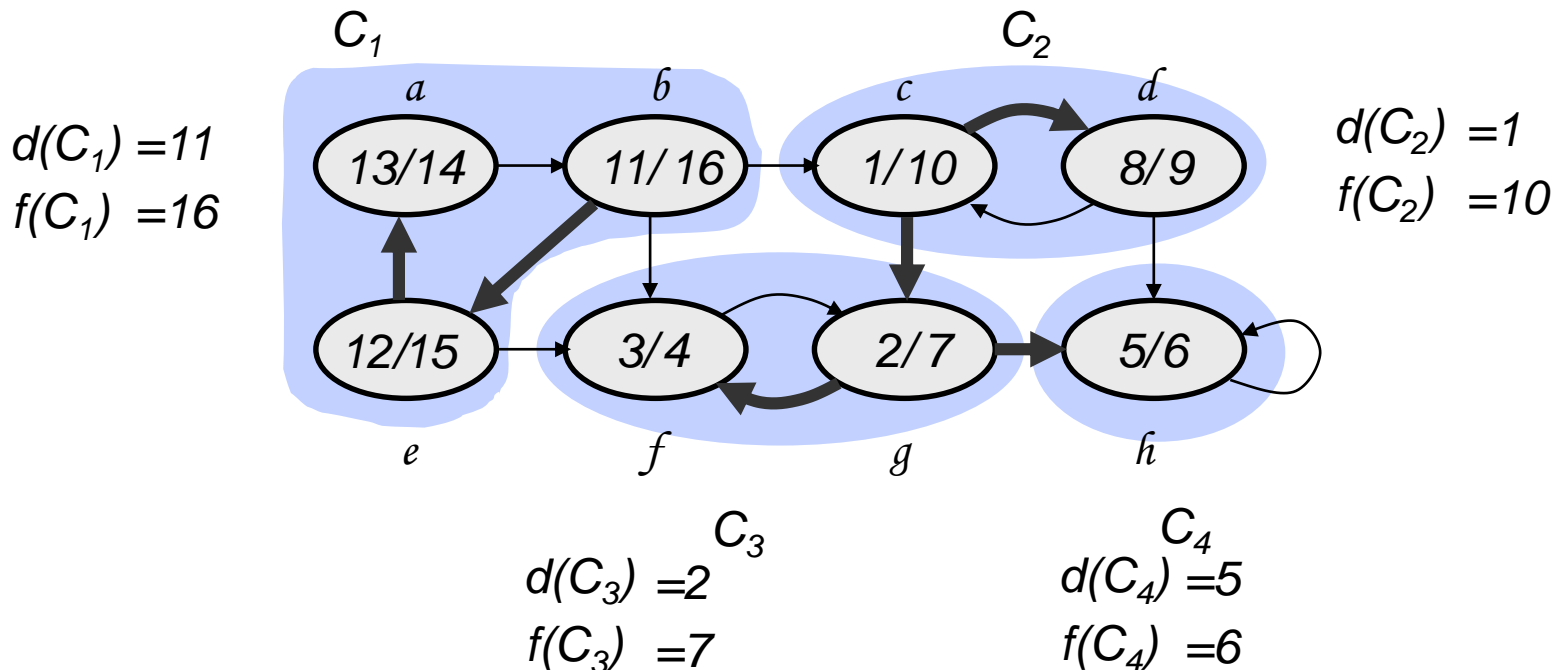

Notations

- Extend notation for d (starting time) and f (finishing time) to sets of vertices $U \subseteq V$:
 - $d(U) = \min_{u \in U} \{ d[u] \}$ (earliest discovery time)
 - $f(U) = \max_{u \in U} \{ f[u] \}$ (latest finishing time)

Lemma 2

- Let C and C' be distinct SCCs in a directed graph $G = (V, E)$. If there is an edge $(u, v) \in E$, where $u \in C$ and $v \in C'$ then $f(C) > f(C')$.
- Consider C_1 and C_2 , connected by edge (b, c)

Corollary

- Let C and C' be distinct SCCs in a directed graph $G = (V, E)$. If there is an edge $(u, v) \in E^T$, where $u \in C$ and $v \in C'$ then $f(C) < f(C')$.
- Consider C_2 and C_1 , connected by edge (c, b)

- Since $(c, b) \in E^T \Rightarrow (b, c) \in E$
- From previous lemma:
 $f(C_1) > f(C_2)$
 $f(C') > f(C)$
 $f(C) < f(C')$

Corollary

- Each edge in G^T that goes between different components goes from a component with an earlier finish time (in the DFS) to one with a later finish time

Why does SCC Work?

- When we do the second DFS, on G^T , we start with a component C such that $f(C)$ is maximum (b , in our case)
- We start from b and visit all vertices in C_1
- From corollary: $f(C) > f(C')$ in G for all $C \neq C' \Rightarrow$ there are no edges from C to any other SCCs in G^T

\Rightarrow DFS will visit only vertices in C_1

\Rightarrow The depth-first tree rooted at b contains exactly the vertices of C_1

Why does SCC Work? (cont.)

- The next root chosen in the second DFS is in SCC C_2 such that $f(C)$ is maximum over all SCC's other than C_1
 - DFS visits all vertices in C_2
 - the only edges out of C_2 go to C_1 , which we've already visited
- ⇒ The only tree edges will be to vertices in C_2
- Each time we choose a new root it can reach only:
 - vertices in its own component
 - vertices in components *already visited*

b	e	a	c	d	g	h	f
16	15	14	10	9	7	6	4
